

PennyLane Support

PennyLane, as a leading quantum machine learning framework, has a growing community of learners working through coding challenges ranging from basic quantum circuits to advanced algorithms.

Challenge for you is to build a community-driven support conversations platform for PennyLane quantum computing challenges that enables learners to seek help, share knowledge, and collaborate on coding challenges through a structured conversation system.

Included within this task are two data files to get you started:

1. [pennylane_coding_challenges.json](#) - which contains data about coding challenges that users are interacting with and trying to solve.
2. [pennylane_support_conversations.json](#) - Which contains support conversation data relating to the coding challenges
3. [Here's the link to the data files](#) that you can work with for this assignment. Feel free to add or update fields as you see fit.

Requirements:

- Create a normalized, scalable database to store & manage coding challenges and related support conversations.
- Provide comprehensive APIs to view coding challenges and manage support conversation data.
 - A user can browse coding challenges and create support conversations.
 - PennyLane support team can view, assign, reply to and manage all support conversations.
- Send us a link to the project's GitHub repository and include instructions to setup and run your application.

Some guidelines:

- Databases and APIs should be clean and efficient to allow different users to browse and interact with the system meaningfully. At Xanadu, we use Python, PostgreSQL, and GraphQL. However, you can choose your preferred tech stack.
- We don't expect you to spend more than a few hours on this.
